## **ВВЕДЕНИЕ**

Целью данного отчёта является предоставление алгоритма расчётов в области знаний «климат», на примере климатических данных метеостанции Фергана за период с 1970 г. по 2006г. По остальным областям знаний отчёты будут представлены в формате, описанном в данном отчёте.

В отчёте представлен алгоритм расчёта эвапотранспирации эталонной культуры на основе измеренных на метеостанции параметров по методу, описанному в ФАО-56 (Эвапотранспирация растений). Аналогичный подход использовался нами в проекте «Сбор irrigation management for combating irrigation induced desertification in the Aral sea basin (CIRMAN-ARAL)» (Контракт: ICA2-CT-2000-10039, 2000-2004 гг.) и используется в программе Профессора Луиса Перейры – “EVAPOT”.

Эвапотранспирация (ET) - это сочетание двух отдельных процессов, при которых почва теряет воду через испарение, а растения - через транспирацию. Оба процесса, испарение и транспирация, происходят одновременно и их несложно отличить. Кроме наличия влаги в почве, для почв, покрытых растительностью, важна часть солнечной радиации, достигающая поверхности. Эта часть уменьшается в вегетационный период, когда кроны растений затеняют все большую площадь. Пока растение маленькое, вода расходуется в основном на испарение с почвы, но по мере развития растение покрывает почти всю площадь и транспирация начинает преобладать (ФАО-56). При посеве почти 100% ET идет через испарение, а при полном развитии растений почти 100% ET идет через транспирацию.

Скорость эвапотранспирации обычно выражается в миллиметрах в единицу времени. Скорость выражает количество воды, потерянной с культивируемой площади в единицах толщины слоя воды (глубины). Единицей времени может быть час, день, декада, месяц или даже целиком вегетационный период.

Поскольку 1 га = 10000 м<sup>2</sup>, а 1 мм = 0,001 м, потеря 1мм означает потерю 10 м<sup>3</sup> воды с гектара. Другими словами, 1 мм/сутки эквивалентен 10 м<sup>3</sup>/га/сутки.

В качестве примера представлены графические материалы, которые могут быть получены на основе обработки климатической информации (Приложение 1).

В Приложении 2 представлены среднедекадные значения метеопараметров м/с «Фергана» за период с января 1970 по декабрь 2000, а в Приложении 3 среднесуточные значения метеопараметров за период с 1 января 2001 по 30 ноября 2006 по данным САНИГМИ.

В Приложении 4 приведен пример расчёта в форматах EXCEL эталонной эвапотранспирации ET<sub>0</sub> для метеостанции «Фергана» (январь-декабрь, 2005) по алгоритмам, представленным в ФАО-56.

## 1. ЭТАЛОННАЯ ЭВАПОТРАНСПИРАЦИЯ (ET<sub>o</sub>)

Скорость эвапотранспирации с эталонной поверхности без дефицита воды называется эталонной эвапотранспирацией и обозначается как ET<sub>o</sub>. За эталонную поверхность принимается гипотетический травяной покров со специфическими характеристиками. Использование других определений, например, потенциальная ET не рекомендуется ввиду возможной путаницы.

Понятие эталонной эвапотранспирации было введено для изучения испарительной потребности атмосферы независимо от вида культур, а также практики их выращивания. Поскольку на эталонной поверхности вода имеется в изобилии, почвенные факторы не влияют на ET. Привязка ET к конкретной поверхности обеспечивает эталон, к которому можно привязать эвапотранспирацию с другой поверхности. Значения ET<sub>o</sub>, измеренные и подсчитанные для различных мест или разных сезонов, являются сравнимыми, так как они привязываются к ET для одной и той же эталонной поверхности.

ET<sub>o</sub> является климатическим параметром и может быть подсчитана исходя из метеоданных. ET<sub>o</sub> выражает испаренную силу атмосферы в конкретной местности и для конкретного времени года и не зависит от сельхозкультур или типа почвы. Метод Пенмана-Монтеята рекомендован как единственный метод определения ET<sub>o</sub>. Он был избран, поскольку он хорошо аппроксимирует ET<sub>o</sub> для травы в исследуемой местности к физически обоснованным и физиологическим и аэродинамическим параметрам.

Таким образом, эталонная эвапотранспирация ET<sub>o</sub> обеспечивает стандарт, с которым:

- можно сравнивать эвапотранспирацию в разные периоды года;
- можно соотнести эвапотранспирацию для других культур.

### *Климатические данные*

Все климатические данные, представленные в отчёте, получены из САНИГМИ.

*Необходимо помнить, что оперативные данные, не проверенные САНИГМИ, не являются основой для корректной обработки этих данных.*

### *Эвапориметр*

Эвапориметр измеряет интегральное воздействие радиации, ветра, температуры и влажности по испарению с открытой водной поверхности. Хотя прибор реагирует одинаково на сходные климатические факторы, влияющие на транспирацию растениями, некоторые факты образуют существенную разницу в потере воды с водной поверхности и орошаемой площади. Отражение солнечной радиации водой в мелкой емкости может отличаться от 23%, принятых для эталонной травяной поверхности. Накопление тепла внутри емкости может вызывать существенное испарение в ночное время, в то время, как транспирация большинства растений происходит лишь в дневное время. Имеются различия и в турбулентности, температуре и влажности воздуха непосредственно над соответствующей поверхностью. Кроме того, имеет место передача тепла через стенки емкости, что влияет на энергетический баланс.

Для сопоставления рассчитанных значений ET<sub>o</sub> и данных по испарению измеренных на испарителе ГГИ-300 (обычно используемому на местных метеостанциях), аналогичном утопленному эвапориметру Колорадо необходимо ввести коэффициент редукции (E<sub>pan</sub>) для ГГИ-300, зависящий от условий проведения измерений испарения. (таблица 1).

Испарение с эвапориметра соотносится с эталонной эвапотранспирацией через эмпирически определенный коэффициент эвапориметра:

$$ET_0 = K_p E_{pan} \quad (\text{уравнение 55, ФАО-56})$$

где:

ET<sub>0</sub> - эталонная эвапотранспирация [мм/сут];

$K_p$  - коэффициент эвапориметра [-];  
 $E_{pan}$  - испарение из эвапориметра [мм/сут].

#### ТАБЛИЦА 1

**Коэффициенты эвапориметра ( $K_p$ ) для утопленных приборов Колорадо для различных случаев установки прибора и окружающей среды, а также различных уровней средней относительной влажности и скорости ветра (публикация ФАО № 24)**

Колорадо	Случай А: прибор установлен на площадке с зеленой сельхозкультурой				Случай В: прибор установлен на сухих заброшенных землях (1)			
	RH <sub>mean</sub> (%) □	низкий < 40	средний 40-70	высокий > 70	низкий < 40	средний 40-70	высокий > 70	
Скорость ветра (м/с)	Расстояние от земной культуры с подветренной стороны (м)				Расстояние от земной культуры с подветренной стороны (м)			
Слабый	1	0,75	0,75	0,8	1	1,1	1,1	1,1
< 2	10	1,0	1,0	1,0	10	0,85	0,85	0,85
	≥100	1,1	1,1	1,1	100	0,75	0,75	0,8
					1000	0,7	0,7	0,75
Умеренный	1	0,65	0,7	0,7	1	0,95	0,95	0,95
2-5	10	0,85	0,85	0,9	10	0,75	0,75	0,75
	≥100	0,95	0,95	0,95	100	0,65	0,65	0,7
					1000	0,6	0,6	0,65
Сильный	1	0,55	0,6	0,65	1	0,8	0,8	0,8
5-8	10	0,75	0,75	0,75	10	0,65	0,65	0,65
	≥100	0,8	0,8	0,8	100	0,55	0,6	0,65
					1000	0,5	0,55	0,6
Очень сильный	1	0,5	0,55	0,6	1	0,7	0,75	0,75
	10	0,65	0,7	0,7	10	0,55	0,6	0,65
> 8	≥100	0,7	0,75	0,75	100	0,5	0,55	0,6
					1000	0,45	0,5	0,55

Использование табличных данных может быть недостаточно для учета всех местных факторов, влияющих на  $K_p$  и тогда необходима подгонка к местным условиям. В связи с этим, рекомендуется соответствующая калибровка  $E_{pan}$  в отношении  $ET_o$ , рассчитанной по методу Пенмана-Монтеята.

## 2. ПЕРЕЧЕНЬ ИЗМЕРЯЕМЫХ МЕТЕОПАРАМЕТРОВ

В таблице 2 и таблице 3 представлен перечень измеряемых метеопараметров, на основе которых рассчитывается ЕТо на основе среднедекадных (табл.2) или среднесуточных (табл.3) метеопараметров. В приложениях 2 и 3 представлены измеренные персоналом метеостанции и проверенные САНИГМИ метеопараметры по метеостанции «Фергана» за период 1970-2006 гг.

Высота метеостанции над уровнем моря равна 582 м, координаты:  $40^{\circ}23'$  с.ш.,  $71^{\circ}45'$  в.д.

**Таблица 2. Перечень декадных метеопараметров**

### 3. АЛГОРИТМ РАСЧЁТА ЭВАПОТРАНСПИРАЦИИ ЭТАЛОННОЙ КУЛЬТУРЫ ПО МЕТОДУ ФАО-56.

Пример расчёта  $ET_0$  в форматах программы Excel представлен в Приложении 4. В алгоритме расчёта использовались нижеприведенные формулы.

Расчёт эвапотранспирации эталонной культуры ( $ET_0$ , мм сут<sup>-1</sup>):

$$ET_0 = \frac{0.408\Delta(R_n - G) + \gamma \frac{900}{T + 273} u_2(e_s - e_a)}{\Delta + \gamma(1 + 0.34u_2)}$$

здесь:

$ET_0$  – эталонная эвапотранспирация (мм сут<sup>-1</sup>);  
 $R_n$  – чистая радиация на поверхности растений (МДж м<sup>-2</sup> сут<sup>-1</sup>);  
 $G$  – плотность теплового потока почвы (МДж м<sup>-2</sup> сут<sup>-1</sup>);  
 $T$  – среднесуточная температура воздуха на высоте 2 м (°C);  
 $u_2$  – скорость ветра на высоте 2 м (м с<sup>-1</sup>);  
 $e_s$  – давление пара насыщения (кПа);  
 $e_a$  – фактическое давление (кПа);  
 $(e_s - e_a)$  – дефицит давления пара насыщения (кПа);  
 $\Delta$  – уклон кривой давления пара (кПа°C<sup>-1</sup>);  
 $\gamma$  – психрометрическая постоянная (кПа°C<sup>-1</sup>)

#### 1. Атмосферное давление ( $P$ )

$$P = 101,3 \left( \frac{293 - 0,0065z}{293} \right)^{5,26} \text{ (уравнение 7 из ФАО-56)}$$

где

$P$  - атмосферное давление [кПа];  
 $z$  - высота над уровнем моря [м].

#### 2. Психрометрическая постоянная ( $\gamma$ )

$$\gamma = \frac{c_p P}{\varepsilon \lambda} = 0,665 \times 10^{-3} P \text{ (формула 8 из ФАО-56)}$$

где

$\gamma$  - психрометрическая постоянная [кПа °C<sup>-1</sup>];  
 $P$  - атмосферное давление [кПа];  
 $\lambda$  - скрытая теплота парообразования, 2,45 [МДж кг<sup>-1</sup>];  
 $c_p$  - удельное тепло при постоянной температуре, 1,013 10<sup>-3</sup> [МДж кг<sup>-1</sup> °C<sup>-1</sup>];  
 $\varepsilon$  - отношение молекулярных весов водяного пара и сухого воздуха = 0,622.

#### 3. Средняя температура воздуха ( $T_{mean}$ ) рассчитывается , как:

$$T_{mean} = \frac{T_{max} + T_{min}}{2} \text{ (уравнение 9 из ФАО-56)}$$

#### 4. Среднее давление пара насыщения ( $e_s$ )

$$e^0(T) = 0,6108 \exp \left[ \frac{17,27 T}{T + 237,3} \right] \text{ (уравнение 11 из ФАО-56)}$$

где

$e^0(T)$  - давление пара насыщения при температуре  $T$  [кПа];  
 $T$  - температура воздуха [°C];  
 $\exp [...]$  - 2,7183 (основание натурального логарифма в степени [...]).

Ввиду нелинейности уравнения (11), среднее давление пара насыщения для суток, недели, декады или месяца должно рассчитываться как среднее между давлением пара насыщения и среднесуточной максимальной и минимальной температурой воздуха для данного периода:

$$e_s = \frac{e^0(T_{\max}) + e^0(T_{\min})}{2} \quad (\text{уравнение 12 из ФАО-56})$$

##### 5. Уклон кривой давления пара ( $\Delta$ )

$$\Delta = \frac{4098 \left[ 0,6108 \exp \left( \frac{17,27T}{T + 237,3} \right) \right]}{(T + 237,3)^2} \quad (\text{уравнение 13 из ФАО-56})$$

где

$\Delta$  - уклон кривой давления пара насыщения при температуре воздуха

$T$  [кПа  ${}^{\circ}\text{C}^{-1}$ ];

$T$  - температура воздуха  ${}^{\circ}\text{C}$ ;

$\exp [...] = 2,7183$  (основание натурального логарифма в степени [...]).

В уравнении Пенмана-Монтейта, где  $\Delta$  находится и в числителе, и в знаменателе, он рассчитывается с использованием средней температуры воздуха ( $T_{\text{mean}}$ ).

##### 6. Дефицит давления пара ( $e_a - e_s$ )

##### 7. Внеземная радиация для дневного периода ( $R_a$ )

$$R_a = \frac{24(60)}{\pi} G_{\text{sc}} d_r [\omega_s \sin(\varphi) + \cos(\varphi) \cos(\delta \cos(\omega_s))] \quad (\text{уравнение 21, ФАО-56})$$

$R_a$  - внеземная радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$G_{\text{sc}}$  - солнечная постоянная = 0,0820  $\text{МДж м}^{-2} \text{ мин}^{-1}$ ;

$d_r$  - обратное относительное расстояние Земля-Солнце (уравнение 23);

$\omega_s$  - угол на закате [рад] (уравнение 25 или 26);

$\varphi$  - широта [рад] (уравнение 22);

$\delta$  - солнечное наклонение [рад] (уравнение 24).

Преобразование из десятичных градусов в радианы производится по формуле:

$$[\text{Радианы}] = \frac{\pi}{180} [\text{десятичные градусы}] \quad (\text{уравнение 22, ФАО-56})$$

Обратное относительное расстояние Земля-Солнце  $d_r$  и солнечное наклонение  $\delta$  равны:

$$d_r = 1 + 0,033 \cos \left( \frac{2\pi}{365} J \right) \quad (\text{уравнение 23, ФАО-56})$$

$$\delta = 0,409 \sin \left( \frac{2\pi}{365} J - 1,39 \right) \quad (\text{уравнение 24, ФАО-56})$$

где  $J$  - количество дней в году между 1 (1 января) и 365 или 366 (31 декабря), значения  $J$  для всех дней в году и уравнение для определения  $J$  даны в приложении 2 (табл. 2.5).

Угол на закате  $\omega_s$  равен

$$\omega_s = \arccos[-\operatorname{tg}(\varphi)\operatorname{tg}(\delta)] \quad (\text{уравнение 25, ФАО-56})$$

Поскольку функция  $\arccos$  присутствует не во всех компьютерных языках, угол заката может быть рассчитан с использованием функции  $\operatorname{arctg}$ :

$$\omega_s = \frac{\pi}{2} - \operatorname{arctg} \left[ \frac{-\operatorname{tg}(\varphi)\operatorname{tg}(\delta)}{X^{0,5}} \right] \quad (\text{уравнение 26, ФАО-56})$$

где

$$X = 1 - [\operatorname{tg}(\varphi)]^2 [\operatorname{tg}(\delta)]^2 \quad (\text{уравнение 27, ФАО-56})$$

и  $X = 0,00001$  если  $X \leq 0$

### 8. Внеземная радиация для часовых или более коротких периодов ( $R_a$ )

$$R_a = \frac{12(60)}{\pi} G_{sc} d_r [(\omega_2 - \omega_1) \sin(\varphi) \sin(\delta) + \cos(\varphi) \cos(\delta) (\sin(\omega_2) - \sin(\omega_1))] \quad (\text{уравнение 28, ФАО-56})$$

где

$R_a$  - внеземная радиация в течение часа (или более короткого) периода  
[МДж  $\text{м}^{-2}$  сут $^{-1}$ ];

$G_{sc}$  - солнечная постоянная = 0,0820 МДж  $\text{м}^{-2}$  мин $^{-1}$ ;

$d_r$  - обратное относительное расстояние Земля-Солнце (ур-е 23);

$\delta$  - солнечное наклонение [рад] (ур-е 24);

$\varphi$  - широта [рад] (ур-е 22);

$\omega_1$  - угол солнечного времени на начало периода [рад] (ур-е 29);

$\omega_2$  - угол солнечного времени на конец периода [рад] (ур-е 30).

Углы солнечного времени на начало и конец периода равны, соответственно:

$$\omega_1 = \omega - \frac{\pi t_1}{24} \quad (\text{уравнение 29, ФАО-56})$$

$$\omega_2 = \omega + \frac{\pi t_1}{24} \quad (\text{уравнение 30, ФАО-56})$$

где

$\omega$  - угол солнечного времени в середине часового (или более короткого) периода [рад];  
 $t_1$  - продолжительность расчетного периода [час], т. е. 1 для 1 часа и 0,5 для 30 минут.

Угол солнечного времени на середину периода равен:

$$\omega = \frac{\pi}{12} [(t + 0,06667(L_z - L_m) + S_c) - 12] \quad (\text{уравнение 31, ФАО-56})$$

где

$t$  - стандартное время в середине периода [час]. Например, для периода между 14.00 и 15.00  $t = 14,5$ ;

$L_z$  - долгота центра зоны местного времени [градусы к западу от Гринвича].

Например,  $L_z = 75^\circ, 90^\circ, 105^\circ$  и  $120^\circ$  для Восточной, Центральной, Роки Маунтин и Тихоокеанской временных зон (США) и  $L_z = 0^\circ$  для Гринвича,  $330^\circ$  для Каира (Египет) и  $255^\circ$  для Бангкока (Таиланд);

$L_m$  - долгота площади измерения [градусы к западу от Гринвича];

$S_c$  - сезонная коррекция солнечного времени [час].

Конечно,  $\omega < -\omega_s$  или  $\omega > \omega_s$  из уравнения (31) показывают, что Солнце находится за горизонтом и  $R_a$  равно 0.

Сезонная коррекция солнечного времени

$$S_c = 0,1645 \sin(2b) - 0,1255 \cos(b) - 0,025 \sin(b) \quad (\text{уравнение 32, ФАО-56})$$

$$b = \frac{2\pi(J-81)}{364} \text{ (уравнение 33, ФАО-56)}$$

где J - количество дней в году.

#### 9. Часы дневного света ( $N$ )

$$N = \frac{24}{\pi} \omega_s \text{ (уравнение 34, ФАО-56)}$$

где  $\omega_s$  - угол часа заката Солнца в радианах из уравнения 25 и 26.

#### 10. Солнечная радиация ( $R_s$ )

$$R_s = \left( a_s + b_s \frac{n}{N} \right) R_a \text{ (уравнение 35, ФАО-56)}$$

где

$R_s$  - солнечная или коротковолновая радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$n$  - фактическая продолжительность солнечного сияния [час];

$N$  - максимально возможная продолжительность солнечного сияния или часов дневного света [час];

$n/N$  - относительная продолжительность солнечного сияния [-];

$R_a$  - внеземная радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$a_s$  - постоянная регрессии, выражающая часть внеземной радиации, достигающую Земли в облачные дни ( $n = 0$ );

$a_s + b_s$  - часть внеземной радиации, достигающая Земли в ясные дни ( $n = N$ ).

#### 11. Солнечная радиация в ясную погоду ( $R_{so}$ )

Расчет  $R_{so}$  при  $n = N$  необходим для определения чистой длинноволновой радиации.

- При высоте, близкой к уровню моря, или когда имеются калиброванные величины  $a_s$  и  $b_s$ :

$$R_{so} = (a_s + b_s) R_a \text{ (уравнение 36, ФАО-56)}$$

где

$R_{so}$  - солнечная радиация в ясную погоду, [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$a_s + b_s$  - часть внеземной радиации, достигающая Земли в ясные дни ( $n = N$ ).

- Когда калиброванные величины  $a_s$  и  $b_s$  отсутствуют:

$$R_{so} = (0,75 + 2 \cdot 10^{-5} z) R_a \text{ (уравнение 37, ФАО-56)}$$

где

$z$  - высота над уровнем моря, [м].

Другие, более сложные определения  $R_{so}$ , включающие эффект водных паров и затененности, обсуждаются в приложении 3 (уравнения 3.14 и 20).

#### Чистая солнечная или чистая коротковолновая радиация ( $R_{ns}$ )

Чистая коротковолновая радиация, получаемая из баланса между приходящей и отраженной солнечной радиацией, равна:

$$R_{ns} = (1 - \alpha) R_s \text{ (уравнение 38, ФАО-56)}$$

где

$R_{ns}$  - чистая солнечная или коротковолновая радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$\alpha$  - альбедо или коэффициент отражения кроны, равный 0,23 для гипотетической эталонной травяной поверхности [-];

$R_s$  - приходящая солнечная радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ].

### 12. Чистая длинноволновая радиация ( $R_{nl}$ )

$$R_{nl} = \sigma \left[ \frac{T_{\max,K}^4 + T_{\min,K}^4}{2} \right] \left( 0,34 - 0,14\sqrt{e_a} \right) \left( 1,35 \frac{R_s}{R_{so}} - 0,35 \right) \quad (\text{уравнение 39, ФАО-56})$$

где

$R_{nl}$  - чистая исходящая длинноволновая радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$\sigma$  - постоянная Стефана-Больцмана [ $4,903 \cdot 10^{-9} \text{ МДж К}^{-4} \text{ м}^{-2} \text{ сут}^{-1}$ ];

$T_{\max,K}$  - максимальная абсолютная температура в течение 24-часового периода [ $K = {}^0\text{C} + 273,16$ ];

$T_{\min,K}$  - минимальная абсолютная температура в течение 24-часового периода [ $K = {}^0\text{C} + 273,16$ ];

$e_a$  - фактическое давление пара [кПа];

$R_s/R_{so}$  - относительная коротковолновая радиация (ограничена значением  $\leq 1,0$ );

$R_s$  - измеренная или расчетная (ур-е 35) солнечная радиация [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$R_{so}$  - расчетная (ур-е 36 или 37) радиация для ясного неба [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ].

### 13. Чистая радиация ( $R_n$ )

$$R_n = R_{ns} - R_{nl} \quad (\text{уравнение 40, ФАО-56})$$

### 14. Почвенный тепловой поток ( $G$ )

$$G = c_s \frac{T_i + T_{i-1}}{\Delta t} \Delta z \quad (\text{уравнение 41, ФАО-56})$$

где

$G$  - почвенный тепловой поток [ $\text{МДж м}^{-2} \text{ сут}^{-1}$ ];

$c_s$  - тепловая емкость почвы [ $\text{МДж м}^{-3} {}^0\text{C}^{-1}$ ];

$T_i$  - температура воздуха во время  $i$  [ ${}^0\text{C}$ ];

$T_{i-1}$  - температура воздуха во время  $i-1$  [ ${}^0\text{C}$ ];

$\Delta t$  - продолжительность временного интервала [сут];

$\Delta z$  - эффективная глубина почвы [м].

#### • Для суточного и 10-дневного периодов:

Поскольку амплитуда теплового потока в течение 1 или 10 дней для эталонной травяной поверхности относительно мала, его можно пренебречь и тогда:

$$G_{day} \approx 0 \quad (\text{уравнение 42, ФАО-56})$$

Далее приведены примеры определения ЕТо по среднесуточным (пример 1) и среднедекадным-среднемесячным (пример 2) метеопараметрам.

**ПРИМЕР 1 (ФАО-56)**

**Определение  $E_{T_0}$  по суточным данным**

**Даны** метеорологические данные, измеренные в июле в Брюсселе (Бельгия), расположеннном на  $50^{\circ}48'$  с. ш. на высоте 100 м над уровнем моря.

-	максимальная температура воздуха ( $T_{\max}$ ) =	21,5	$^{\circ}\text{C}$
-	минимальная температура воздуха ( $T_{\min}$ ) =	12,3	$^{\circ}\text{C}$
-	максимальная относительная влажность ( $RH_{\max}$ ) =	84	%
-	минимальная относительная влажность ( $RH_{\min}$ ) =	63	%
-	скорость ветра на высоте 10 м =	10	км/ч
-	продолжительность солнечного сияния (n) =	9,25	час/сут

**Преобразование скорости ветра**

стандартной высоте	Скорость ветра $u_2$	2,078	м/с
--------------------	----------------------	-------	-----

**Параметры**

Из ур-я 7:	Высота = $P =$	100 100,1	м кПа
-	$T_{\text{mean}} = (21,5 + 12,3)/2 =$	16,9	$^{\circ}\text{C}$
Из ур-я 13:	$T_{\text{mean}} =$ $\Delta =$	16,9 0,122	$^{\circ}\text{C}$ кПа/ $^{\circ}\text{C}$
Из ур-я 8:	$P =$ $\gamma =$	100,1 0,0666	кПа кПа/ $^{\circ}\text{C}$
-	$(1 + 0,34 u_2) =$	1,71	-

<b>Эталонная эвапотранспирация травы</b>			
-	$0,408 (R_n - G) \Delta/[\Delta + \gamma (1 + 0,34 u_2)] =$	2,81	мм/сут
-	$900/(T+273) (e_s - e_a) \gamma/[\Delta + \gamma (1 + 0,34 u_2)] =$	1,07	мм/сут
-	$ET_o = 2,81 + 1,07 = 3,88 \approx$	3,9	мм/сут
Эталонная эвапотранспирация травы равна 3,9 мм/сут			

## ПРИМЕР 2 (ФАО-56)

Определение  $ET_o$  по десятидневным или месячным временным интервалам.

Даны средние месячные климатические данные для апреля для Бангкока (Филиппины), расположенного на  $13^{\circ}44'$  с. ш. на высоте 2 м над уровнем моря.

-	Месячная среднесуточная максимальная температура ( $T_{max}$ ) =	34,8	$^{\circ}\text{C}$
-	Месячная среднесуточная минимальная температура ( $T_{min}$ ) =	25,5	$^{\circ}\text{C}$
-	Месячное среднесуточное давление пара ( $e_a$ ) =	2,85	кПа
Измеренная на высоте 2 м	Месячная среднесуточная скорость ветра ( $u_2$ ) =	2	м/с
-	Месячная среднесуточная продолжительность солнечного сияния ( $n$ ) =	8,5	час/сут
Для апреля	Среднемесячная температура ( $T_{month,i}$ ) =	30,2	$^{\circ}\text{C}$
Для марта	Среднемесячная температура ( $T_{month,i-1}$ ) =	29,2	$^{\circ}\text{C}$

Определение по описанию в боксе 11 (расчетная таблица  $ET_o$ )

Параметры			
- Из табл. 2.4 или ур-я 13:	$T_{mean} = [(T_{max} = 34,8) + (T_{min} = 25,6)]/2 =$ $\Delta =$	30,2 0,246	$^{\circ}\text{C}$ кПа/ $^{\circ}\text{C}$
Из табл. 2.1 и 2.2 или ур-й 7 и 8:	Высота = $P =$ $\gamma =$	2 101,3 0,0674	м кПа кПа/ $^{\circ}\text{C}$
-	$(1 + 0,34 u_2) =$	1,68	-
-	$\Delta/[\Delta + \gamma (1 + 0,34 u_2)] = 0,246/[0,246 + 0,0674 (1,68)] =$	0,685	-
-	$\gamma/[\Delta + \gamma (1 + 0,34 u_2)] = 0,0667/[0,246 + 0,0674 (1,68)] =$	0,188	-
-	$900/(T_{mean}+273) u_2 =$	5,94	-

### Дефицит давления пара

Из табл. 2.3 или ур-я 11:	$T_{max} =$ $e^0(T_{max}) =$	34,8 5,56	$^{\circ}\text{C}$ кПа
Из табл. 2.3 или ур-я 11:	$T_{min} =$ $e^0(T_{min}) =$	25,6 3,28	$^{\circ}\text{C}$ кПа
- дано:	$e_s = (5,56 + 3,28)/2 =$ $e_a =$	4,42 2,85	кПа кПа
-	Дефицит давления пара ( $e_s - e_a$ ) = (4,42 - 2,85) =	1,57	кПа

### Радиация (месяц - апрель)

Из табл. 2.6 или 2.5 или ур-я 21:	$J =$ (для 15 апреля) Широта = $13^{\circ}44'$ с. ш. = $(13 + 44/60) =$ $R_a =$	105 13,73 38,06	- $^{\circ}\text{с. ш.}$ $\text{МДж м}^{-2}\text{сут}^{-1}$
N (табл. 2.7 или ур-е 34):	Продолжительность дня N =	12,31	час
-	$n/N = (8,5/12,31) =$	0,69	-
-	$R_s = [0,25 + 0,50 (0,69)] 38,06 =$	22,65	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$R_{so} = (0,75 + 2 (2)/100 000) 38,06 =$	28,54	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$R_s/R_{so} = (22,65/28,54) =$	0,79	-

-	$R_{ns} = 0,77 (22,65) =$	17,44	$\text{МДж м}^{-2}\text{сут}^{-1}$
Из табл. 2.8:	$T_{\max} =$ $\sigma T_{\max,K}^4 =$	34,8 44,10	${}^{\circ}\text{C}$ $\text{МДж м}^{-2}\text{сут}^{-1}$
Из табл. 2.8:	$T_{\min} =$ $\sigma T_{\min,K}^4 =$	25,6 39,06	${}^{\circ}\text{C}$ $\text{МДж м}^{-2}\text{сут}^{-1}$
-	$(\sigma T_{\max,K}^4 + \sigma T_{\min,K}^4)/2 = (44,10 + 39,06)/2 =$	41,58	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$e_a =$ $(0,34 - 0,14 \sqrt{e_a})$	2,85 0,10	кПа -
-	$R_s/R_{so} =$ $(1,35 R_s/R_{so} - 0,35) =$	0,79 0,72	- -
-	$R_{nl} = 41,58 (0,10) 0,72 =$	3,11	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$R_n = (17,44 - 3,11) =$	14,33	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$G = 0,14 (30,2 - 29,2) =$	0,14	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$(R_n - G) = (14,33 - 0,14) =$	14,19	$\text{МДж м}^{-2}\text{сут}^{-1}$
-	$0,408 (R_n - G) =$	5,79	мм/сут
<b>Эталонная эвапотранспирация травы</b>			
-	$0,408 (R_n - G) \Delta / [\Delta + \gamma (1 + 0,34 u_2)] =$ $(5,79) 0,685 =$	39,7	мм/сут
-	$900 u_2 / (T+273) (e_s - e_a) \gamma / [\Delta + \gamma (1 + 0,34 u_2)] =$ $5,94 (1,57) 0,188 =$	1,75	мм/сут
-	$ET_o = (3,97 + 1,75) =$	5,72	мм/сут
Эталонная эвапотранспирация травы равна 5,7 мм/сут			

## Приложение 1

### Графическое представление климатических данных по метеостанции «Фергана»

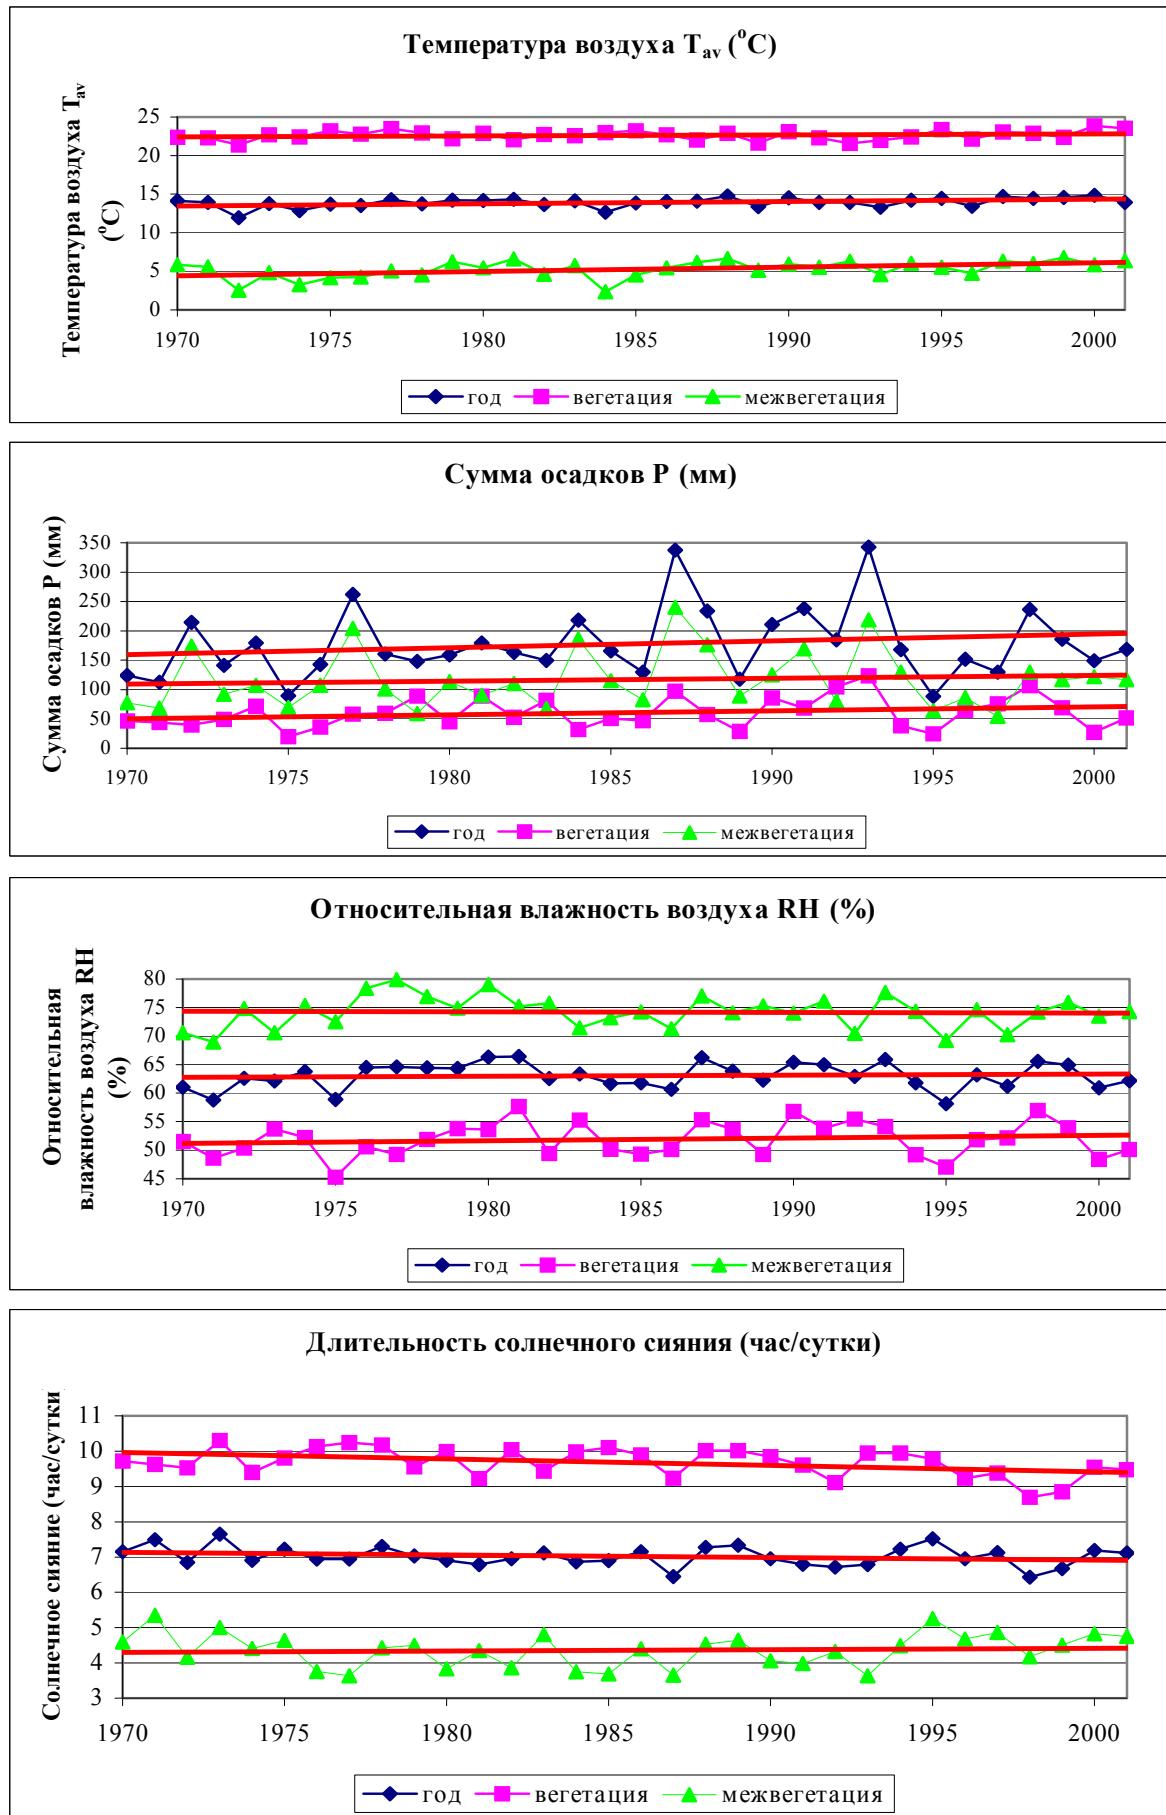

Рис. 1а. Динамика изменения основных метеопараметров (м/с «Фергана» 1970-2001 гг.)

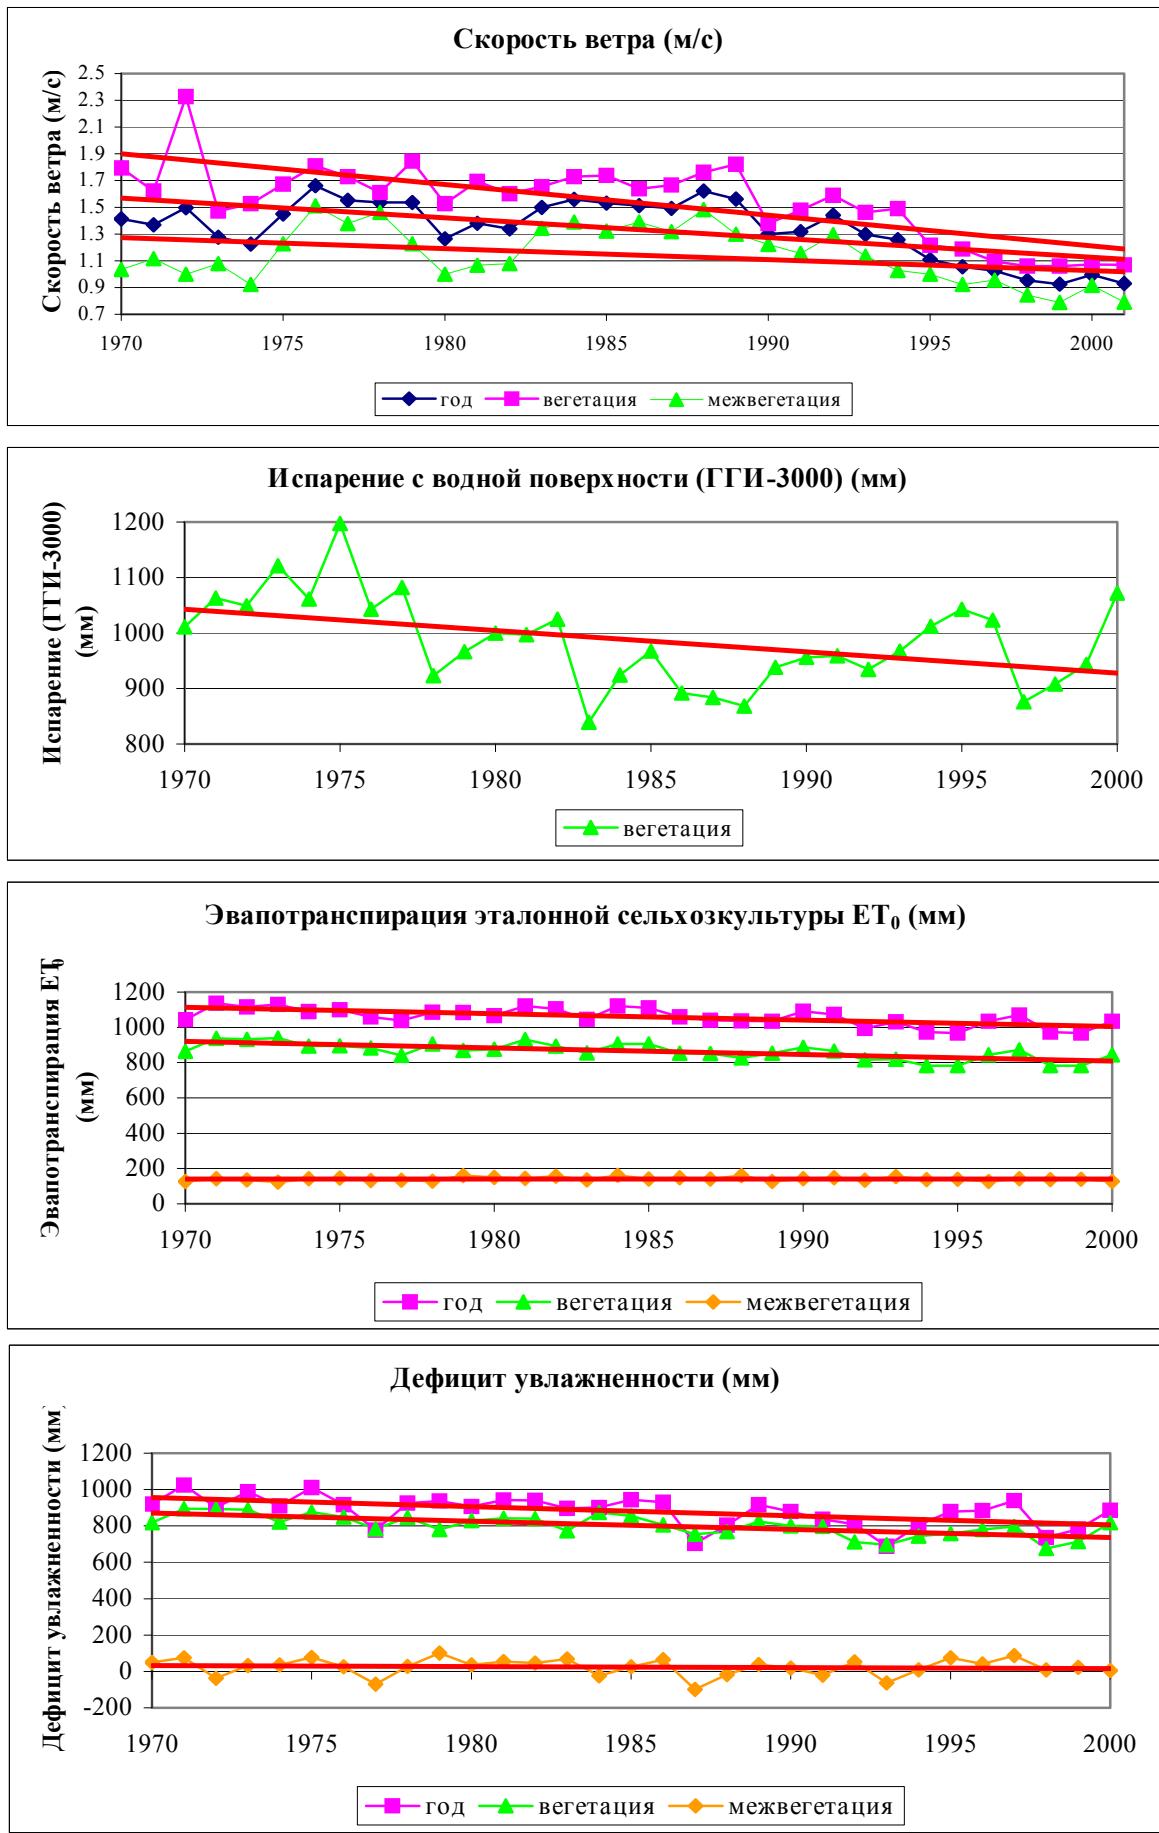

Рис. 2б. Динамика изменения основных метеопараметров (м/с «Фергана» 1970-2001 гг.)

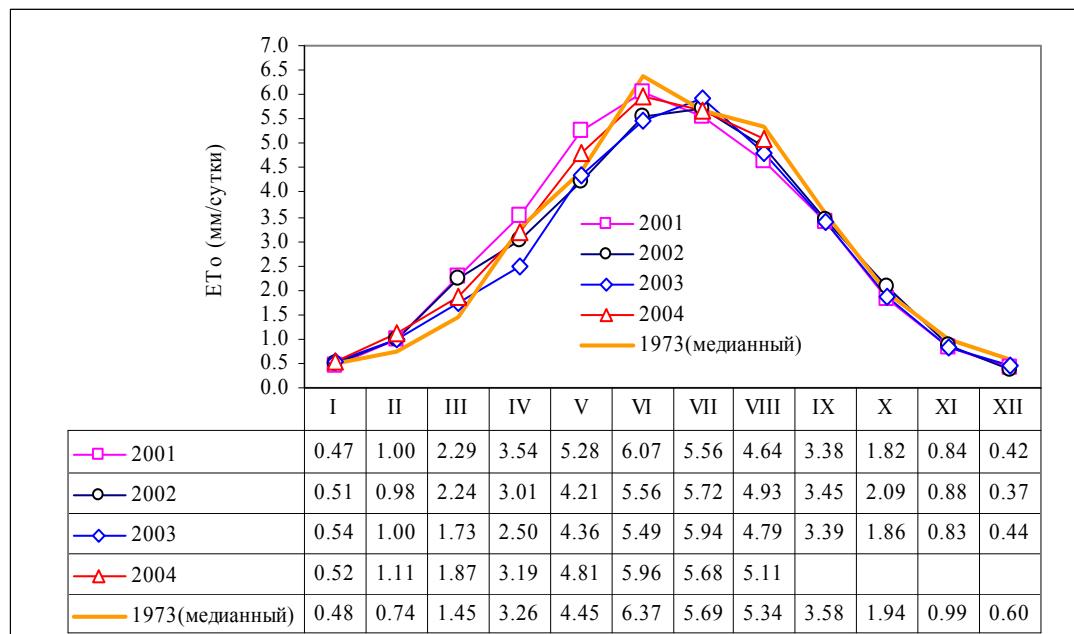

Рис.3. Динамика эвапотранспирации эталонной сельхозкультуры в период 2001-2004гг

### Дефицит увлажненности

Дефицит увлажненности (Рис.4, таблица 1) представлен разностью между эвапотранспирацией эталонной сельхозкультуры и атмосферными осадками:

$$D_{\text{wet}} = ET_o - P$$

где:  $D_{\text{wet}}$  – дефицит увлажненности;  $ET_o$  суммарная эвапотранспирация;  $P$  –атмосферные осадки.

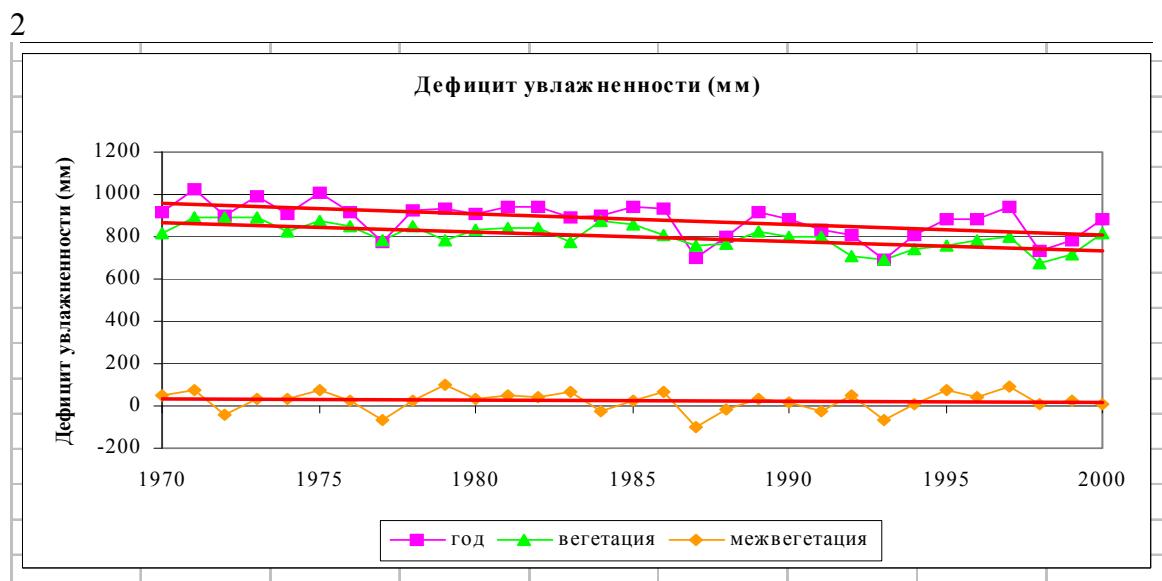

Рис.4 Дефицит увлажнённости [мм] за период 1970-2000 гг.

Таблица 1 - Характеристика дефицита увлажненности на основе данных метеостанции «Фергана» за период 1970-2003 гг.

Год	Дефицит увлажненности (период IV-IX)	Эвапотранспирация эталонной сельхозкультуры (период IV-IX)	Атмосферные осадки (период IV-IX)
	Dwet	ЕТо	P
	мм	мм	мм
1970	853	899	46
1971	845	889	44
1972	866	906	40
1973	827	876	49
1974	793	865	72
1975	919	939	20
1976	898	933	36
1977	881	939	58
1978	833	893	60
1979	807	895	89
1980	838	884	45
1981	753	842	89
1982	853	906	53
1983	787	868	82
1984	843	875	32
1985	881	931	51
1986	846	893	47
1987	758	855	97
1988	848	906	58
1989	877	906	29
1990	768	853	86
1991	784	852	68
1992	722	826	105
1993	729	853	124
1994	849	887	38
1995	841	866	25
1996	751	816	65
1997	744	819	76
1998	676	782	107
1999	714	783	69
2000	818	845	27
2001	818	869	52
2002	731	821	90
2003	653	809	156

Используя аналогичный, как при оценке водообеспеченности, подход можно определить характерные годы обеспеченности дефицита увлажненности из ряда 1970-2004 гг. (рисунки 5 и 6) и (таблица 2).

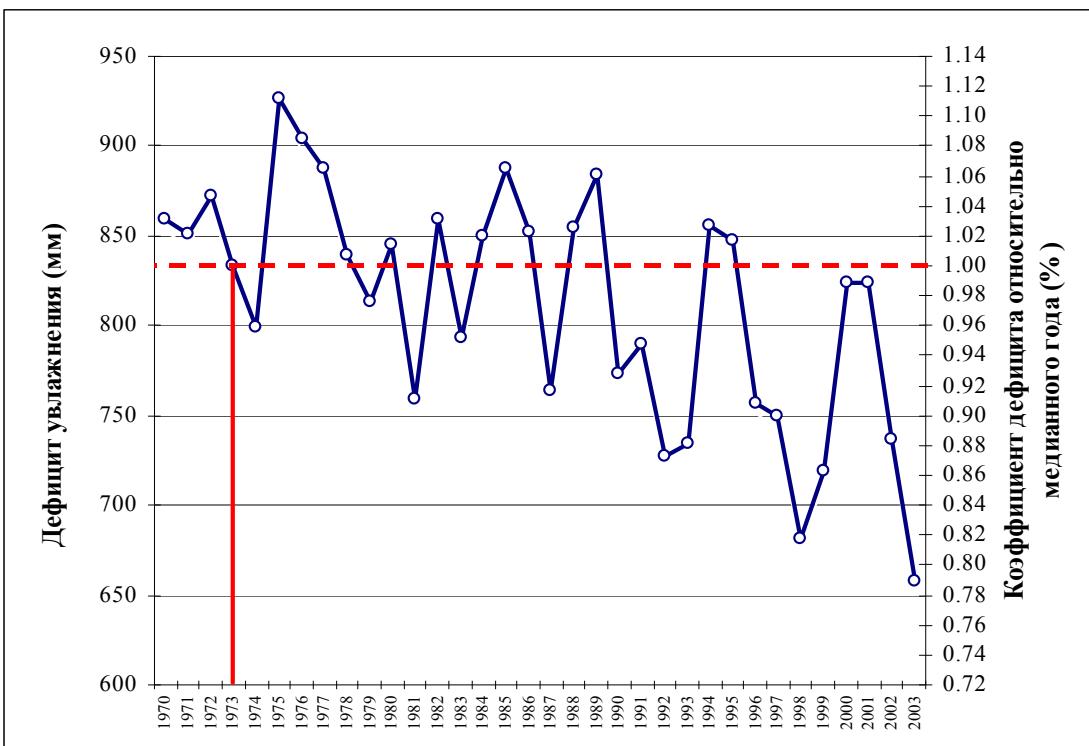

Рисунок 5 - Дефицит увлажненности и коэффициент дефицита относительно медианного года (хронология)

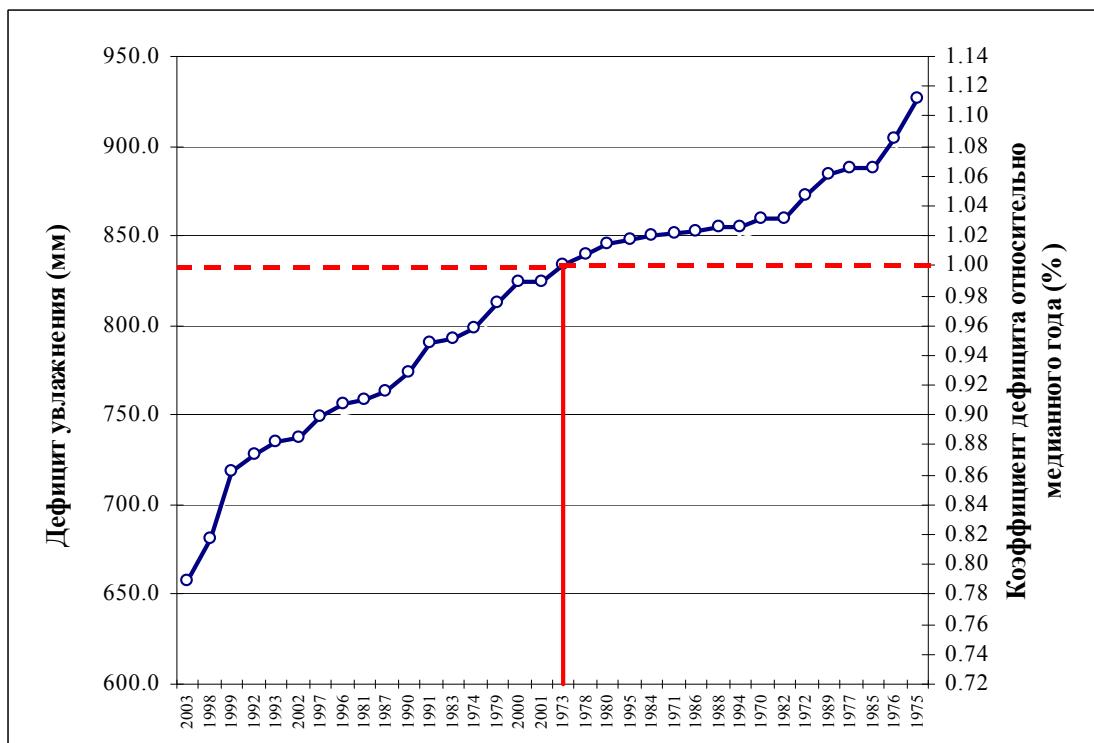

Рисунок 6 - Дефицит увлажненности и коэффициент дефицита относительно медианного года (ранжирование)

Таким образом, медианным годом по увлажненности в период 1970-2004 гг. являлся 1973 г., очень засушливым – 1975 г. и очень влажным – 2003 г. (таблица 2 и рисунок 7).

Таблица 2- Характеристика лет разной обеспеченности дефицита увлажненности

Год	Дефицит увлажненности в период вегетации	m	p <sub>m</sub> (%)	Характеристика лет разной обеспеченности	Коэффициент уменьшения/увеличения дефицита относительно медианного года
	мм		%		
1975	919	1	1	очень сухой	0.89
1976	898	2	4	сухой	0.91
1994	849	9	25	средней сухости	0.97
<b>1973</b>	<b>827</b>	<b>17</b>	<b>49</b>	<b>медианный</b>	<b>1.00</b>
1981	753	26	75	средней влажности	1.09
1998	676	33	96	влажный	1.18
2003	653	34	99	очень влажный	1.21

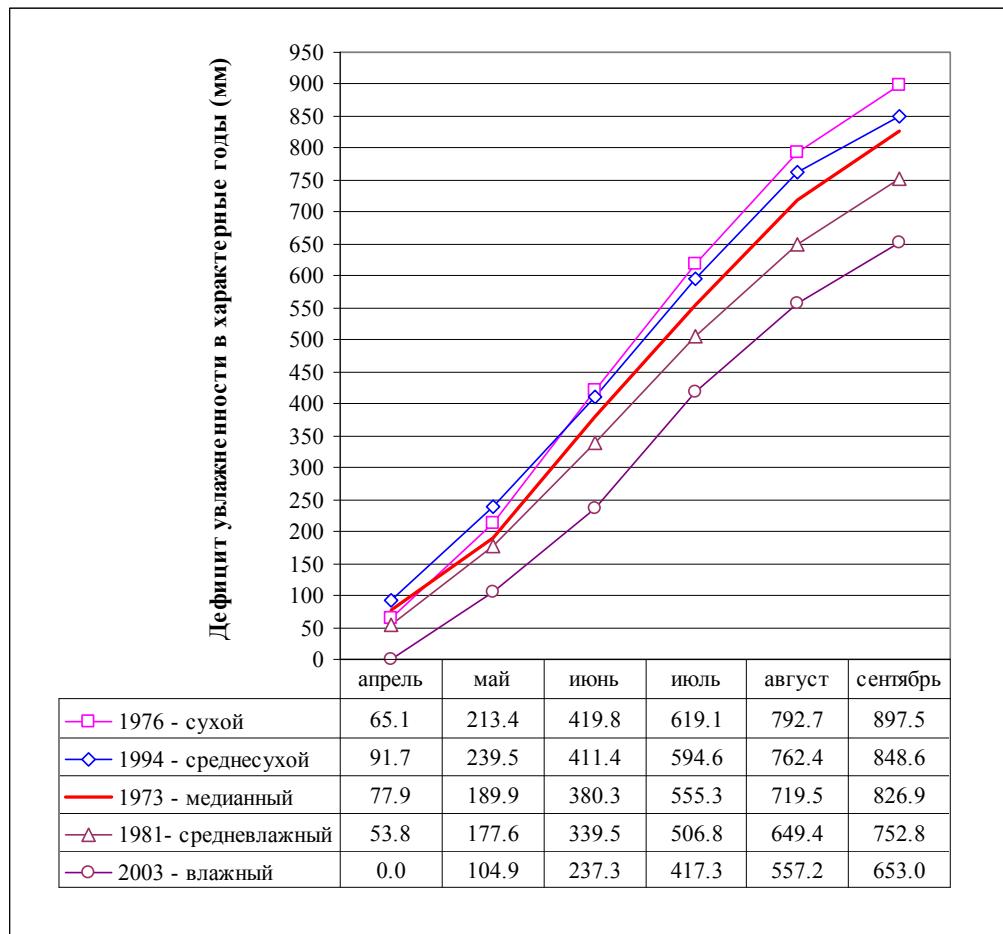

Рисунок 7 - Дефицит увлажненности в характерные годы (период 1970-2003)

## Метеостанция: Ферганা

## Страна : Р. Узбекистан
